In Brief

While anti-cytokine therapies show promising results in autoimmune diseases, its effects on cardiovascular disease development are not well understood. Fatkhullina and colleagues show that inactivation of IL-23-IL-22 signaling leads to deterioration of the intestinal barrier, expansion of proatherogenic bacteria, and production of metabolites promoting macrophage activation and atherosclerosis.

SUMMARY

Although commensal flora is involved in the regulation of immunity, the interplay between cytokine signaling and microbiota in atherosclerosis remains unknown. We found that interleukin (IL)-23 and its downstream target IL-22 restricted atherosclerosis by repressing pro-atherogenic microbiota. Inactivation of IL-23-IL-22 signaling led to deterioration of the intestinal barrier, dysbiosis, and expansion of pathogenic bacteria with distinct biosynthetic and metabolic properties, causing systemic increase in pro-atherogenic metabolites such as lipopolysaccharide (LPS) and trimethylamine N-oxide (TMAO). Augmented disease in the absence of the IL-23-IL-22 pathway was mediated in part by pro-atherogenic osteopontin, controlled by microbial metabolites. Microbiota transfer from IL-23-deficient mice accelerated atherosclerosis, whereas microbial depletion or IL-22 supplementation reduced inflammation and ameliorated disease. Our work uncovers the IL-23-IL-22 signaling as a regulator of atherosclerosis that restrains expansion of pro-atherogenic microbiota and argues for informed use of cytokine blockers to avoid cardiovascular side effects driven by microbiota and inflammation.

INTRODUCTION

Atherosclerosis is a lipid-driven, chronic inflammatory disease mediated by activated immune cells in the arterial wall (Galkina

and Ley, 2009). A cross talk between the innate and adaptive immune cells, and non-hematopoietic cells in the aortic wall, is mediated by a number of cytokines, which regulate atherogenesis (Ait-Oufella et al., 2011; Hansson and Hermansson, 2011). Elevated concentration of specific cytokines in human and rodent plasma and aortic tissue are linked to atherosclerosis progression (Caligiuri et al., 2003; Han et al., 2010). Anti-cytokine therapies show promising results in many autoimmune diseases, including inflammatory bowel disease (IBD), psoriasis and arthritis (Gaffen et al., 2014) and, recently, atherosclerosis (Ridker et al., 2017).

Interleukin (IL)-23 is a member of the IL-6-IL-12 family of cytokines and a heterodimer of p19 (unique) and p40 (shared with IL-12) subunits. The IL-23 cytokine axis drives several chronic inflammatory diseases, including arthritis, psoriasis, IBD, and cancer; and genetic inactivation or pharmacological blockade of IL-23 generally suppresses disease development (Cua et al., 2003; Hue et al., 2006). IL-23 is a known regulator of IL-17A and IL-22 cytokine production (Gaffen et al., 2014). The role of IL-17A in atherosclerosis has been extensively investigated (Taleb et al., 2010). The mechanisms of IL-22 action in atherosclerosis remain largely unknown, although it has been reported that IL-22 suppresses metabolic disorders and regulates lipid metabolism in the liver and adipose tissue (Behnsen et al., 2014; Wang et al., 2014a). An elevated IL-23 has been reported in aortic tissue of mice and humans with cardiovascular diseases (CVD) (Abbas et al., 2015), while it is reduced in PBMCs of patients with CVD (Khojasteh-Fard et al., 2012). IL-23 has also been implicated in the regulation of cardiac inflammation, as *II23^{-/-}* mice display increased injury and adverse remodeling after myocardial infarction (Savvatis et al., 2014). Although data in other inflammatory models suggest that IL-23 might potentially function to promote atherosclerosis, the exact role of this cytokine remains unknown.

Microbial and viral components of commensal and pathogenic flora (collectively "microbiome") are key emerging factors that regulate cytokine production and differentiation of cytokine-producing cells (Ivanov et al., 2009; Khosravi and Mazmanian, 2013). Emerging evidence demonstrates that commensal microbiota have direct effects on immune system activation and inflammatory responses, playing a key role in regulating chronic inflammatory diseases, including rheumatoid arthritis, IBD and, recently, atherosclerosis (Jonsson and Bäckhed, 2017). Microbiome alterations might systemically impact the progression of distant disease via produced metabolites that increase cardiovascular risk (Jonsson and Bäckhed, 2017). Therefore, changes in gut microbiota caused by dietary factors, stress, or use of antibiotics, may profoundly impact the development of chronic inflammatory diseases, potentially including atherosclerosis. To date, the mechanisms controlling the interplay between diet, cytokine and immune signaling, and microbiota in atherosclerosis are largely unknown.

Here, we uncovered an atheroprotective role of IL-23-IL-22 signaling. We found that IL-23 and IL-22 shape gut microbiota by regulating the production of antimicrobial peptides and restraining the expansion of the semi-invasive bacterial species with pro-atherogenic properties. Metagenomic sequencing and metabolomics along with functional experiments demonstrated that these bacteria promoted atherosclerosis progression particularly by producing lipopolysaccharide (LPS) and components of the trimethylamine N-oxide (TMAO) biosynthesis pathway, upregulating the expression of pro-atherogenic osteopontin (OPN) and facilitating the activation of Ly6C^{hi} monocytes and aortic macrophages. Using genetic, pharmacological, and other approaches, we delineated the mechanisms of cvtokine microbiota-mediated pathway that distantly controls atherosclerosis progression. Our data argues for informed application and further clinical studies of IL-23 and especially IL-22 blockers in individuals with sub-optimal dietary habits and those predisposed to atherosclerosis.

RESULTS

IL-23 Deficiency Aggravates Atherosclerosis

IL-23 cytokine and its downstream target IL-17A have been implicated in the pathogenesis of several autoimmune diseases (Gaffen et al., 2014) and cancer (Grivennikov et al., 2012). The fact that IL-23 regulates pro-atherogenic IL-17A led us to hypothesize that IL-23 might be pathogenic in atherosclerosis. Because both IL-23 and its cognate receptor IL-23R are primarily expressed within the hematopoietic compartment, we used a bone marrow (BM) chimera approach to ablate IL-23 signaling in hematopoietic cells in an atherosclerosis-prone mouse model. Age, gender, litter, and cage matched atherosclerosis-prone Ldlr-1- mice were lethally irradiated and transplanted with BM from either C57BL/6 (wild type, WT), *ll23p19^{-/-} (ll23^{-/-})*, or *ll23r^{-/-}* mice, followed by 16 weeks of a Western Diet (WD) feeding. Atherosclerotic plaque sizes were analyzed in isolated aortic roots stained with Oil Red O. Macroscopic and histological analysis revealed an unexpected significant increase in atherosclerotic plaque sizes in $II23^{-/-} \rightarrow Ldlr^{-/-}$ mice compared to $WT \rightarrow Ldlr^{-/-}$ controls (Figures 1A-1C). No differences in lipid profile, body weight, or blood leukocyte counts were detected between cohorts (Figure S1A-C). To corroborate these findings, we tested whether IL-23R deficiency phenocopies IL-23 loss. Indeed, $II23r^{-/-} \rightarrow Ldlr^{-/-}$ mice developed significantly more atherosclerosis compared to WT $\rightarrow Ldlr^{-/-}$ counterparts (Figure S1D). This strong exacerbation of atherosclerosis upon genetic ablation of either IL-23 cytokine or its receptor and suggests an unexpected protective role of IL-23 signaling.

To determine whether IL-23 mediated suppression of atherosclerosis is a general phenomenon, we analyzed disease progression in genetic crosses of $Ldlr^{-/-} \times ll23^{-/-}$ and $Apoe^{-/-} \times ll23^{-/-}$ mice. Similar to BM transplanted mice, both $Ldlr^{-/-} \times ll23^{-/-}$ and $Apoe^{-/-} \times ll23^{-/-}$ mice developed significantly larger atherosclerotic lesions (Figures S1E and S1F). Therefore, the atheroprotective action of IL-23 is general, not limited to the BM chimera approach and is observed in two separate mouse models of atherosclerosis.

Flow cytometry and immunofluorescence revealed increased accumulation of multiple types of hematopoietic cells (CD45⁺), including CD4⁺ T cells (TCR β ⁺CD4⁺) and myeloid cell subsets (CD11b⁺, CD11c⁺, CD11b⁺CD11c⁺) in aortas of $II23^{-/-} \rightarrow LdIr^{-/-}$ mice (Figure 1D and S2A-B). Additionally, Q-RT-PCR analysis of inflammatory gene expression showed a significant upregulation of II1b, Tnf, the chemokines Ccl2, Ccl5, and Cxcl1, as well Cd36 genes in the aortas of $II23^{-/-} \rightarrow Ldlr^{-/-}$ mice compared to WT \rightarrow Ldlr^{-/-} controls (Figure 1E). Since IL-23 is known to regulate the production of IL-17A by T helper and ILC3 cells, we assayed IL-17A by Q-RT-PCR and intracellular cytokine staining. We did not find any differences in IL-17A between $II23^{-/-} \rightarrow Ldlr^{-/-}$ and WT \rightarrow Ldlr^{-/-} mice (Figure 1E and Figure S2C) suggesting that IL-23 may be dispensable for its expression in the atherosclerotic aorta. As previous studies have demonstrated that IL-23 is required for regulating intestinal inflammation (Ahern et al., 2010), we examined inflammatory gene expression in the intestine of mice with atherosclerosis. Consistently, we found a reduction of II1b, Tnf, Ccl2, Ccl5, Cxcl1, and Il22 gene expression in the intestines of $II23^{-/-} \rightarrow Ldlr^{-/-}$ mice compared to WT \rightarrow Ldlr^{-/-} controls (Figure 1F and Figure S2D). Overall, these findings suggest that IL-23 signaling suppresses atherosclerosis.

Inactivation of IL-22 Exacerbates Atherosclerosis

Because IL-23 is also known to regulate IL-22 expression (Zheng et al., 2008) and IL-22 was downregulated in $II23^{-/-} \rightarrow Ldlr^{-/-}$ mice, we next asked whether IL-22 also protects from atherosclerosis. We found strong exacerbation of atherosclerosis in $II22^{-/-} \rightarrow$ $Ldlr^{-/-}$ mice compared to WT $\rightarrow Ldlr^{-/-}$ littermate and cagemate WD-fed controls (Figures 2A-2C). $II22^{-/-} \rightarrow LdIr^{-/-}$ mice were characterized by an increased accumulation of T cells and myeloid cells (Figures 2D and S2E and S2F) in the aortas, and by an upregulation of inflammatory gene expression in aortas and intestines (Figures 2E and 2F). Transfer of IL-22 deficient BM resulted in strong downregulation of intestinal IL-22 (Figure S2G). We also observed that IL-22-producing CD90.2+ ILC3 and T cells were almost exclusively donor-derived (Figure S2H), thereby excluding incomplete BM repopulation or IL-22 production by residual radio-resistant cells. In agreement with our observation of enhanced atherosclerosis in $II23^{-/-} \rightarrow Ldlr^{-/-}$ and $II22^{-/-} \rightarrow Ldlr^{-/-}$ mice, we found an increased number of apoptotic cells (Figure S3A) and smooth muscle cells (Figure S3B) in the aortas. No difference was detected in tissue repair macrophage genes, IL-12 or lipid transporters expression (Figures S3C–S3E).

Figure 1. Aggravated Atherosclerosis and Increased Immune Cells Infiltration in Aortas of IL-23 Deficient Mice

(A) Images of aortic arch from Ldlr^{-/-} mice transplanted with I/23^{-/-} or WT BM and fed with WD for 16 weeks.

(B and C) Representative images of aortic root sections (B) and quantitative comparison of atherosclerotic lesion size (C) of $ll23^{-r} \rightarrow Ldlr^{-r}$ (n = 13) or WT $\rightarrow Ldlr^{-r}$ (n = 13) mice.

(D) Immune cell composition of aortas isolated from $ll23^{-/-} \rightarrow Ldlr^{-/-}$ (n = 13) and WT $\rightarrow Ldlr^{-/-}$ (n = 11) was analyzed by flow cytometry. Percentage (left panel) and absolute cell number (right panel) of CD45⁺ hematopoietic cells, and among them CD11b⁺, CD11b⁺CD11c⁺, and CD11c⁺ myeloid cells and CD4⁺ among TCR β^+ cells.

(E and F) Relative gene expression in the aortas (E) and intestines (F) of $ll23^{-/-} \rightarrow Ldlr^{-/-}$ (n = 8) and WT $\rightarrow Ldlr^{-/-}$ (n = 8) mice. Gene expression was normalized to *RpL32* and then to gene expression in WT $\rightarrow Ldlr^{-/-}$ mice. Data are mean \pm SEM from at least 3 independent experiments. *p<0.05, **p<0.001, ***p<0.0001. Student's t-test. See also Figures S1–S3.

To examine whether IL-23 may restrain atherosclerosis via direct induction of IL-22, we performed a "gain-of-function" experiment, testing whether *in vivo* supplementation of IL-22 would rectify the pro-atherogenic effects of IL-23 deficiency.

We administered IL-22 (mIL-22-Ig) to $II23^{-/-} \rightarrow Ldlr^{-/-}$ and WT $\rightarrow Ldlr^{-/-}$ mice (Figure 2G) and observed that $II23^{-/-} \rightarrow Ldlr^{-/-}$ mice receiving mIL-22-Ig developed smaller atherosclerotic lesions compared to controls, while the effect in mIL-22-Ig treated

WT \rightarrow Ldlr^{-/-} mice was less prominent (Figures 2H and 2I). Collectively, these data implicate IL-22 as an immediate IL-23 target in atherosclerosis.

Inactivation of IL-23 or IL-22 Drives Dysbiosis and Pro-Atherogenic Microbiota Alterations

WD can alter microbiota and induce the outgrowth of potentially pathogenic species. Inflammatory cytokines, including IL-23 and IL-22, are known to regulate the function of intestinal epithelial cells and their antimicrobial responses (Zheng et al., 2008). Therefore, we tested whether IL-23 or IL-22 deficiency altered the microbiome and epithelial homeostasis in WD-fed, atherosclerosis-prone mice. We found that intestines of WD-fed $II23^{-/-} \rightarrow Ldlr^{-/-}$ and $II22^{-/-} \rightarrow Ldlr^{-/-}$ mice displayed a significant reduction of the anti-microbial peptides Reg3b and Reg3g expression compared to WT \rightarrow Ldlr^{-/-} controls (Figure 3A). Immunostaining revealed RegIII $\!\gamma$ downregulation, as well as a strong reduction in Mucin2, a key component of mucus (Figure 3B). Ex vivo en face YoYo1 dye DNA staining of whole-mount colon and scanning electron microscopy (SEM) demonstrated elevated numbers of bacteria in close proximity to gut epithelium in $II23^{-/-} \rightarrow Ldlr^{-/-}$ and $II22^{-/-} \rightarrow Ldlr^{-/-}$, but not in WT $\rightarrow Ldlr^{-/-}$ mice (Figure S4A). No significant difference was found in gene expression of tight junction proteins or intestinal permeability (data not shown). Therefore, IL-23 or IL-22 ablation in WD-fed mice reduces protective, anti-microbial peptides, and results in altered localization of bacteria.

To determine whether the exacerbation of atherosclerosis in $II23^{-/-} \rightarrow Ldlr^{-/-}$ and $II22^{-/-} \rightarrow Ldlr^{-/-}$ mice is mediated by distinct gualitative and guantitative alterations in gut flora, we performed whole metagenome shotgun sequencing analysis of microbiota littermate and cagemate mice co-housed for the entire length of experiment. While global comparison of cecal luminal microbial communities revealed differences between the microbiomes of $II23^{-/-} \rightarrow Ldlr^{-/-}$, $II22^{-/-} \rightarrow Ldlr^{-/-}$ and $WT \rightarrow Ldlr^{-/-}$ mice at the bacteria species level as demonstrated by principal component analysis (Figure 3C), much greater similarities between $II23^{-/-} \rightarrow$ $Ldlr^{-/-}$ and $ll22^{-/-} \rightarrow Ldlr^{-/-}$ mice versus controls were found at a higher taxonomical level. In particular, the families Enterobacteriaceae (Klebsiella sp), Prevotellaceae (Prevotella copri), and Lachnospiraceae, Clostridiaceae, and Ruminococcaceae (Figure 3D) were enriched in both $ll23^{-/-} \rightarrow Ldlr^{-/-}$ and $ll22^{-/-} \rightarrow Ldlr^{-/-}$ mice. These bacterial families have been suggested to be pro-inflammatory or pro-atherogenic (Elinav et al., 2011; Fu et al., 2015; Gregory et al., 2015; Kelly et al., 2016). We found high similarities in enzyme commission (EC) numbers analysis (enzymatic activities) (Figures 3E and 3F) of luminal bacteria between $II23^{-/-} \rightarrow LdIr^{-/-}$ and $II22^{-/-} \rightarrow LdIr^{-/-}$ in contrast to WT $\rightarrow LdIr^{-/-}$ controls. Particularly, it revealed an increased presence of the bacterial gene encoding for choline-trimethylamine lyase, an enzyme, required for trimethylamine (TMA) production (Wang et al., 2015).

To further confirm whether downregulation of anti-microbial peptides and mucus allows bacteria to locate close to intestinal epithelial cells, we analyzed changes in adherent microbiota in isolated washed intestinal tissue. Q-RT-PCR analysis revealed an increase in 16S rRNA in $II23^{-/-} \rightarrow Ldlr^{-/-}$ and $II22^{-/-} \rightarrow Ldlr^{-/-}$ mice, indicating accumulation of epithelium-adhesive bacteria (Figure 3G). 16S rRNA sequencing of tissue-adhesive microbiota supported the Q-RT-PCR observations and demonstrated an overrepresentation of *Clostridiaceae*, *Verrucomicrobiaceae*, *Lachnospiraceae*, and other families in the epithelium of $II23^{-/-} \rightarrow Ldlr^{-/-}$ mice (Figure 3H).

To functionally address whether the progression of atherosclerosis is indeed driven by cytokine-dependent changes in microbiota, we treated randomized $II23^{-/-} \rightarrow Ldlr^{-/-}$ and $II22^{-/-} \rightarrow$ Ldlr^{-/-} mice with a mix of broad-spectrum antibiotics in drinking water for the last 4 weeks of WD feeding (Figure 4A). As anticipated, antibiotics markedly depleted intestinal microbes (Figure S4B) and resulted in a significant reduction in atherosclerotic plaque size in the $l/23^{-/-} \rightarrow Ldlr^{-/-}$ and $l/22^{-/-} \rightarrow Ldlr^{-/-}$ mice. compared to untreated mice of the same genotype (Figures 4B and 4C). Both groups of antibiotic-treated mice showed a significant reduction in the expression of pro-inflammatory genes in the aorta and intestine (Figures 4D and S4C). Conversely, "microbiota transfer" experiments revealed that microbial communities isolated from WD-fed $II23^{-/-} \rightarrow Ldlr^{-/-}$ mice promoted atherosclerosis and inflammatory gene expression in aortas of $WT \rightarrow Ldlr^{-/-}$ mice (Figures 4E–4H and S4D). Microbiota transfer also affected intestinal gene expression (Figure S4E) similarly to found in BM transplanted mice (Figure 1F). Importantly, reciprocal transfer of "wild-type microbiome" was unable to suppress the disease in $II23^{-/-} \rightarrow Ldlr^{-/-}$ mice (Figures 4E–4G and S4D and S4F). These data indicate that microbiota from $II23^{-/-} \rightarrow Ldlr^{-/-}$ mice possesses specific disease-inducing abilities that can be transferred to the wild type host. 16S rRNA sequencing revealed that fecal transplant from $II23^{-/-} \rightarrow Ldlr^{-/-}$ donors increased the amount of Clostridiaceae, Lachnospiraceae, and Ruminococcaceae in WT \rightarrow Ldlr^{-/-} recipients (Figure S5A–S5C) and reduced anti-microbial peptides expression (Figure S4E), similarly to

Figure 2. Ablation of IL-22 Exacerbates Atherosclerosis and IL-22 Administration Suppresses the Disease Development in IL-23-Deficient Mice

(G) Scheme of experiment. II/23^{-/-} → LdIr^{-/-} and WT → LdIr^{-/-} were administered with mIL-22-Ig for 4 weeks starting at 8 weeks of WD feeding.

⁽A–C) Images of aortic arch from $LdIr^{-r}$ mice transplanted with $II22^{-r}$ or WT BM and fed with WD for 16 weeks. Representative images of aortic root sections and quantitative comparison of atherosclerotic lesion size of $II22^{-r} \rightarrow LdIr^{-r}$ (n=16) or WT $\rightarrow LdIr^{-r}$ (n=12) mice.

⁽D-F) Immune cell composition of aortas isolated from $II22^{-/-} \rightarrow LdIr^{-/-}$ (n = 7) and WT $\rightarrow LdIr^{-/-}$ (n = 5) was analyzed by flow cytometry. Percentage (left panel) and absolute cell number (right panel) of CD45⁺ hematopoietic cells, and among them CD11b⁺, CD11b⁺CD11c⁺, and CD11c⁺ myeloid cells and CD4⁺ among TCR β^+ cells. Relative gene expression in the aortas (E) and intestines (F) of $II22^{-/-} \rightarrow LdIr^{-/-}$ (n=8) or WT $\rightarrow LdIr^{-/-}$ (n=8) mice was normalized to *RpL32* and then to gene expression in WT $\rightarrow LdIr^{-/-}$ mice.

⁽H) Representative images of aortic root sections and quantitative comparison of atherosclerotic lesion size from $ll23^{-/-} \rightarrow Ldlr^{-/-}$ (n = 13 [control], n = 12 [mlL-22-lg]) and WT $\rightarrow Ldlr^{-/-}$ (n = 9 [control], n = 8 [mlL-22-lg]) mice treated with mlL-22-lg or control. Data are mean ± SEM from 3 independent experiments. *p<0.05, **p<0.001, ***p<0.0001. Student's t-test.

⁽I) IF representative image from 3 independent experiments of aortic root sections from $ll23^{-/-} \rightarrow Ldlr^{-/-}$ or WT $\rightarrow Ldlr^{-/-}$ mice after mIL-22-Ig treatment demonstrates the reduction of CD11b⁺, CD11c⁺, and CD11b⁺CD11c⁺ myeloid cells. A-adventitia, M-media, P-plaque. See also Figures S2 and S3.

 $ll23^{-/-} \rightarrow Ldlr^{-/-}$ mice. No significant difference was found in $ll23^{-/-} \rightarrow Ldlr^{-/-}$ recipients of WT microbiota (Figure S4F).

Therefore, IL-23 and IL-22 are required to regulate intestinal homeostasis to prevent outgrowth of pathogenic bacteria and excessive accumulation of bacteria in a close proximity to the epithelium. The exacerbated atherosclerosis observed in the absence of IL-23 or IL-22 is driven directly by microbes, as the atherosclerotic phenotype is accompanied by changes in luminal and mucosa-associated microbes is "transferrable" to WT recipient by microbiota from IL-23-deficient donor and can be reversed by microbiota ablation.

Inactivation of IL-23 or IL-22 Leads to an Increase in Metabolites with Pro-Atherogenic Properties

Although upregulated bacterial operational taxonomic units (OTUs) were not always identical between $II23^{-/-} \rightarrow Ldlr^{-/-}$ and II22-/-→Ldlr-/- mice, initial Picrust analysis of 16S rRNA sequencing data suggested that multiple bacterial pathways were strongly upregulated in both $II23^{-/-} \rightarrow LdIr^{-/-}$ and $II22^{-/-} \rightarrow$ $Ldlr^{-/-}$ mice compared to WT $\rightarrow Ldlr^{-/-}$ controls (data not shown). These bacterial pathways, including LPS biosynthesis, N-glycosylation, and specific lipid biosynthesis, have been suggested to be pro-inflammatory (Hornemann and Worgall, 2013). A protein domains structure prediction, performed on metagenomic sequencing data, demonstrated the upregulation of the LPS biosynthesis as the most significantly changed pathway (Figures 5A–5C), therefore, suggesting that the disruption of IL-23-IL-22 signaling leads to the enrichment of bacterial species capable of producing pro-inflammatory metabolites. This enrichment in bacteria and their closer adherence to the epithelium may allow release of the bacterial metabolites into the systemic circulation. thereby promoting atherosclerosis. In agreement with this idea, we found elevated LPS in sera of both IL-23- and IL-22-deficient Ldlr^{-/-} mice (Figure 5D), implying that the expansion of pathogenic flora may contribute to low-grade systemic inflammation. Importantly, administration of mIL-22-Ig, which "rescues" the IL-23-deficient phenotype (Figure 2H), also reduced serum LPS (Figure 5E) along with "normalizing" microbiota (Figure S5D). Consistently, microbiota depletion by antibiotics reduced serum LPS concentration (Figure 5F), while fecal transplant from IL-23-deficient atherosclerotic donors increased it in WT \rightarrow *Ldlr*^{-/-} mice (Figure 5G).

Next, to characterize additional mechanistic cues originating from the microbiota and promoting atherosclerosis, we performed discovery metabolomics on serum samples from $II23^{-/-} \rightarrow Ldlr^{-/-}$, $II22^{-/-} \rightarrow Ldlr^{-/-}$, and $WT \rightarrow Ldlr^{-/-}$ mice fed with WD for 16 weeks. We detected an increased presence of metabolites related to trimethylamine N-oxide (TMAO) production, including phosphatidylcholine, choline, betaine, and trimethylamine (TMA) (Figure 5I), as well as others (Figure S6). These results were in line with an increased presence of bacterial genes encoding for choline-trimethylamine lyase (a TMA biosynthesis enzyme) in $II23^{-/-} \rightarrow Ldlr^{-/-}$ and $II22^{-/-} \rightarrow Ldlr^{-/-}$ mice (Figure 5H). A similar upregulation of TMAO pathway metabolites was detected in WT \rightarrow Ldlr^{-/-} recipients of fecal microbiota from IL-23deficient donors (Figure 5I and S6D). The chemical detection of these metabolites was consistent with metagenome shotgun analysis and 16S rRNA sequencing of luminal and adhesive bacteria, which revealed overrepresentation of bacteria associated with TMAO pathway metabolism and increased presence of choline trimethylamine lyase bacterial gene (Figure 3D, 3H, 5H). Importantly, TMAO serum concentrations were further elevated in *Ldlr^{-/-} x ll23^{-/-}* mice fed with WD diet containing 1% choline, a direct metabolic precursor, which is converted into TMAO by bacteria dependent mechanisms (Figure 5J).

Overall, these data suggest a mechanistic connection between disrupted IL-23-IL-22 cytokine signaling, a reduction in colonic epithelial barrier function, expansion of pathogenic microbiota, elevated bacteria-derived metabolites in the serum, and atherosclerosis progression, perhaps via induction of lowgrade inflammation.

Osteopontin Upregulation Links Microbial Changes to Progression of Atherosclerosis

To further determine how the cytokine ablation and dysbiosis affect inflammatory responses in the aortas, we analyzed inflammatory gene expression and found osteopontin (OPN, *Spp1*) as highly upregulated gene in aortas of $II23^{-/-} \rightarrow LdIr^{-/-}$ and $II22^{-/-} \rightarrow LdIr^{-/-}$ mice (Figure 6A). OPN, a secreted inflammatory protein, has been implicated in various inflammatory conditions and suggested to play a role in atherosclerosis (Isoda et al., 2003; Kahles et al., 2014; Matsui et al., 2003). We found that OPN protein was highly expressed in CD11b⁺CD11c⁻ macrophages in the aortas (Figure 6B), while its expression was modest in macrophages

Figure 3. IL-23 or IL-22 Deficiency Reduces Antimicrobial Peptide Expression and Contributes to Microbiome Alterations in the Gut of Atherosclerotic Mice

(A) Relative antimicrobial peptide gene expression in the intestines of WT \rightarrow *Ldlr*^{-/-} (n=6), *ll23*^{-/-} \rightarrow *Ldlr*^{-/-} (n = 6) and *ll22*^{-/-} \rightarrow *Ldlr*^{-/-} (n = 6) mice was normalized to *RpL32* and then to gene expression in WT \rightarrow *Ldlr*^{-/-} mice. Data are mean ± SEM from 3 independent experiments. *p<0.05, **p<0.001, ***p<0.0001. Student's t-test.

(B) Representative IHC staining of RegIII γ in colon tissue of WT $\rightarrow Ldhr^{-/-}$, $ll23^{-/-} \rightarrow Ldhr^{-/-}$, or $ll22^{-/-} \rightarrow Ldhr^{-/-}$ mice (top panel), scale bar is 100 μ m. Representative mucin staining in colon tissue sections of WT $\rightarrow Ldhr^{-/-}$, $ll23^{-/-} \rightarrow Ldhr^{-/-}$ mice stained for Mucin2 (green) and DAPI (blue) (middle panel), scale bar is 100 μ m. Mucin layer staining after Carnoy's Fixation (bottom panel), scale bar is 50 μ m. Images are representative from 3 independent experiments.

(C) Microbiome compositions in $II23^{-r} \rightarrow Ldlr^{-r}$ and $II22^{-r} \rightarrow Ldlr^{-r}$ mice compared to WT $\rightarrow Ldlr^{-r}$ cage mate controls as determined by whole metagenome shotgun sequencing followed by principal component analysis (PCA).

Figure 4. Cytokine-Mediated Alterations in Microbiota Drive Atherosclerosis Progression in $II23^{-/-} \rightarrow LdIr^{-/-}$ and $II22^{-/-} \rightarrow LdIr^{-/-}$ Mice (A) Scheme of experiment. WT $\rightarrow LdIr^{-/-}$, $II23^{-/-} \rightarrow LdIr^{-/-}$, or $II22^{-/-} \rightarrow LdIr^{-/-}$ mice fed with WD for 16 weeks were maintained for the last 4 weeks of WD feeding on regular (Reg) or broad-spectrum antibiotic (Abx) containing water.

in other tissues, including peritoneal cavity or spleen (data not shown).

Next, we found that microbiota depletion by antibiotics led to a significant downregulation of Spp1 in $II23^{-/-} \rightarrow Ldlr^{-/-}$ and $II22^{-/-} \rightarrow$ $Ldlr^{-/-}$ mice (Figure 6C), while microbiota transfer from $ll23^{-/-} \rightarrow$ $Ldlr^{-/-}$ donors induced Spp1 expression in WT $\rightarrow Ldlr^{-/-}$ recipients (Figure 6D), suggesting that a particular constellation of microbial compounds, available in IL-23-deficient mice, is capable to induce OPN. To mechanistically test whether OPN is an important mediator of atherosclerosis aggravation, we treated randomized II23^{-/-} \rightarrow LdIr^{-/-}, II22^{-/-} \rightarrow LdIr^{-/-}, and WT \rightarrow LdIr^{-/-} mice with anti-OPN antibody for the last 2.5 weeks of WD feeding (Figure 6E). OPN neutralization significantly reduced atherosclerosis in both $ll23^{-/-} \rightarrow Ldlr^{-/-}$ and $ll22^{-/-} \rightarrow Ldlr^{-/-}$ mice, bringing disease manifestations to those observed in WT \rightarrow Ldlr^{-/-} controls (Figures 6F and 6G). We found a significant reduction in myeloid and T cells in the aortic roots of both $ll23^{-/-} \rightarrow Ldlr^{-/-}$ and $II22^{-/-} \rightarrow LdIr^{-/-}$ mice treated with anti-OPN antibody (Figure 6H and S7A-S7C). This reduction of inflammatory cells was accompanied by downregulation of II1b, Ccl2, and Ccl5 in anti-OPNtreated $II23^{-/-} \rightarrow Ldlr^{-/-}$ and $II22^{-/-} \rightarrow Ldlr^{-/-}$ mice (Figure 6I).

Finally, we tested whether metabolites elevated in IL-23- and IL-22-deficient mice could directly promote OPN expression and atherosclerosis progression. We treated mice for 3 weeks with LPS and TMAO and found that combined administration of these metabolites accelerated atherosclerosis development in WD-fed Ldlr^{-/-} mice (Figures 7A and 7B) along with upregulation of Spp1, Cd36, and II1b gene expression in aortas (Figure 7C). Similar results were obtained when explanted aortas were stimulated with LPS and TMAO ex vivo (Figure S7D). We further found that acute in vivo administration of LPS and TMAO enhances Spp1 expression in circulating Ly6C^{hi} monocytes (Figure 7D), suggesting that OPN may become upregulated in circulating cells. It is conceivable that these pre-activated monocytes are then recruited to atherosclerotic plaques, where they differentiate into macrophages and produce more OPN in an environment rich in OPN-inducing stimuli.

Together, these data suggest that OPN is an important driver of atherosclerosis and its expression is regulated by pathogenic microbiota and metabolites, which are kept at bay by a functional IL-23-IL-22 pathway. Altogether, a functional atheroprotective IL-23-IL-22 axis maintains intestinal homeostasis and normal host-microbe interactions, and prevents outgrowth of epitheliaassociated, pro-atherogenic bacteria. These bacteria deliver pro-atherogenic metabolites, such as LPS and TMAO systemically due to the defective intestinal barrier. These metabolites conspire with additional pro-atherogenic factors to enhance the activation of circulating monocytes and pathogenic inflammatory macrophages promoting atherosclerosis, particularly in OPN-dependent manner.

DISCUSSION

A field connecting the diet-modulated microbiome and metabolic diseases has recently emerged. Microbial alterations have been shown to regulate cytokine production, which is required for host defense against intestinal infections (Belkaid and Hand, 2014). Conversely, cytokine signaling has been also implicated in the regulation of host-microbiome interactions during infections (Kamada et al., 2013). Because atherosclerosis is an inflammatory disease, it could be expected that cytokine blockade, which has been effective in multiple forms of autoimmunity, might be beneficial against this chronic CVD condition as exemplified by the recently completed CANTOS trial (Ridker et al., 2017). However, the fact that cytokines are important regulators of host-microbial interactions provides an alternative possibility, namely that cytokine blockade will alter distinct qualitative and quantitative characteristic of the microbiota, further affecting metabolic parameters. Both of these possibilities were largely unexplored, especially for a cytokine like IL-23, whose role in atherosclerosis remains elusive.

Our work reveals that cytokine signaling, which plays a key role in driving systemic inflammation, is also involved in homeostatic regulation of intestinal epithelial cells, controlling expansion of atherogenic microbiota. We have shown that genetic inactivation of either IL-23 or its receptor, IL-23R, aggravated atherosclerosis progression in a long-term model, which allows microbiota alterations to develop and microbiota-driven changes to manifest. In previous studies, systemic expression of IL-23 in a transgenic model induced an inflammatory phenotype and promoted various inflammatory diseases, predisposing to atherosclerosis (Wiekowski et al., 2001). Short-term IL-23 iniections have been shown to increase apoptosis in plaques. likely acting in a GM-CSF-dependent manner, and it was shown that early lesions could develop unperturbed in the absence of IL-23R (Engelbertsen et al., 2018; Subramanian et al., 2015). In our model, genetic inactivation of IL-23 resulted in an increased number of apoptotic cells in atherosclerotic plaques, confirming that apoptosis in the plaque is tightly linked to atherosclerosis progression.

While we originally hypothesized that IL-23 would regulate IL-17A expression in the aorta and thereby would promote atherosclerosis in IL-17A-dependent manner, we did not find any differences in IL-17A expression in the aortas of IL-23- or

⁽B and C) Representative images of aortic root sections and quantitative comparison of atherosclerotic lesion size in $WT \rightarrow Ldhr^{-/-}$ (n = 8 [Reg], n = 5 [Abx]), $ll23^{-/-} \rightarrow Ldhr^{-/-}$ (n = 9 [Reg], n = 6 [Abx]), or $ll22^{-/-} \rightarrow Ldhr^{-/-}$ (n = 12 [Reg], n = 6 [Abx]) mice maintained on regular or antibiotic water. Data are average from 3 independent experiments.

(A–C) Protein domain structure prediction for luminal bacteria from $ll23^{-/-} \rightarrow Ldlr^{-/-}$, $ll22^{-/-} \rightarrow Ldlr^{-/-}$, and WT $\rightarrow Ldlr^{-/-}$ mice as determined by metagenome shotgun sequencing.

(A) Principal component analysis (PCA).

IL-23R-deficient mice. Other factors, for instance, IL-1 β strongly upregulated in the aortas of $II23^{-/-} \rightarrow Ldlr^{-/-}$ mice, could in turn promote IL-17A production in the absence of IL-23. On the other hand, we found a significant reduction of IL-22 expression, another cytokine regulated by IL-23, in the intestines of atherosclerotic $I/23^{-/-} \rightarrow Ldlr^{-/-}$ mice. Our data revealed that IL-22 had a strong protective role in atherosclerosis, as $II22^{-/-} \rightarrow Ldlr^{-/-}$ mice developed exacerbated disease compared to $WT \rightarrow$ Ldlr^{-/-} controls, although a pro-atherogenic role of this cytokine was also previously suggested (Rattik et al., 2015). Administration of IL-22 suppressed the disease in IL-23-deficient mice, implying IL-22 as a critical mediator downstream of IL-23. The observed differences in phenotypes may be attributed to several factors, including possible genetic variations between the mice used or differences in the microbiome of non-cohoused and non-littermate animals, supporting the hypothesis that IL-22 has an important microbiome-regulatory role in atherosclerosis.

Cytokine signaling in intestinal epithelial cells has been suggested to modulate microbiota composition (Belkaid and Hand, 2014; Kamada et al., 2013). IL-22 has been found to control epithelial cell proliferation and antimicrobial peptide production, limiting the ability of commensal bacteria to cause inflammation (Behnsen et al., 2014; Sugimoto et al., 2008). Changes in the production of anti-microbial peptides therefore can result in the expansion of bacterial species with potentially pathogenic properties and their localization in direct proximity to intestinal epithelium. In agreement, we found a significant reduction of RegIII γ and Mucin 2 in $II22^{-r} \rightarrow Ldlr^{-t}$ and $II23^{-t} \rightarrow$ $Ldlr^{-t}$ atherosclerotic mice, which correlated with a high amount of tightly adhesive bacteria including *Clostridiaceae* and *Ruminococcaceae* known to contribute to mucus layer degradation (Desai et al., 2016; Tailford et al., 2015).

Quantitative alterations of the microbiome have been associated with diseases, including IBD, metabolic disorders, cancer, and atherosclerosis (Elinav et al., 2011; Goodman and Gordon, 2010; Wang et al., 2011). We found that the augmented atherosclerosis progression in WD-fed $II23^{-/-} \rightarrow LdIr^{-/-}$ and $II22^{-/-} \rightarrow LdIr^{-/-}$ mice was associated with the enrichment in bacteria with previously suggested pro-inflammatory and pro-atherogenic roles (Kelly et al., 2016; Wang et al., 2015). Conversely, potentially protective *Odoribacteriaceae* were detected in WT $\rightarrow LdIr^{-/-}$, but not $II23^{-/-} \rightarrow LdIr^{-/-}$ mice. As microbiome alterations could systemically impact distant disease progression via release of metabolites (Postler and Ghosh, 2017; Schroeder and Bäckhed, 2016), we found that the IL-23-IL-22-microbiota axis was essential for regulating several rele-

vant bacterial functional and metabolic pathways, and thus, atherosclerosis. One large group of these pathways increased the adhesiveness of bacteria, the synthesis of toxic bacterial products such as N-glycans, and the sphingolipid biosynthesis pathway. LPS biosynthesis, however, was the highest among the upregulated pathways. Deterioration of epithelial barrier function and adhesiveness of bacteria to the epithelium, combined with elevated biosynthesis of these metabolites, is likely to functionally contribute to the increased systemic concentration of LPS detected in atherosclerotic mice with IL-23 or IL-22 ablation. Alterations of other pathways, found by metagenomics shotgun sequencing were also confirmed by discovery metabolomics detecting elevated presence of phosphatidylcholine, choline, TMA and trimethylamine-N-oxide (TMAO) in serum of $II23^{-/-} \rightarrow Ldlr^{-/-}$ mice. Among them, TMAO has been implicated in the pathogenesis of atherosclerosis in humans and mice consuming a choline-rich diet (Wang et al., 2011). Increased TMAO production in the absence of IL-23 pathway was further elevated by feeding with choline rich WD, implying that IL-23-IL-22-microbiota-TMAO pathway may be especially important in individuals with different sub-optimal dietary habits. Serum TMAO positively correlated with enrichment for certain bacteria, including the Prevotellaceae, Enterobacteriaceae, Ruminococcaceae, and Clostridiaceae, linked to TMAO production and atherosclerosis progression in correlation studies in humans (Brusca et al., 2014; Fu et al., 2015; Gregory et al., 2015; Kelly et al., 2016; Yan et al., 2017). Moreover, metagenomics data revealed increased presence of the bacterial gene encoding for choline-trimethylamine lyase in IL-23 and IL-22 deficient mice, providing linear connection between dysbiosis, pathogenic metabolites, and atherosclerosis. The data obtained from the bacterial pathways analysis might be highly relevant to humans, who are much more diverse in microbes and might harbor pathogenic and protective microbes of different species, but with similar metabolic and biosynthetic profiles.

While metabolites like TMAO and LPS can potentially drive atherosclerosis directly, they can also regulate inflammatory intermediates essential for disease pathogenesis. Indeed, enhanced atherosclerosis in the absence of IL-23-IL-22 pathway was accompanied by increased systemic inflammation. We found strong upregulation of osteopontin (*Spp1*) in circulating Ly6C^{hi} monocytes and CD11b⁺CD11c⁻ aortic macrophages in the absence of IL-23 or IL-22 signaling. OPN is known to be induced by inflammatory, atherosclerosis-relevant stimuli, such as oxidized lipoproteins (oxLDL) and various inflammatory cytokines (Kahles et al., 2014). OPN regulates the recruitment and

Images are representative from 2 independent experiments. Data are mean \pm SEM. Student's t-test. *p<0.05, **p<0.001. See also Figure S7.

which could be observed upon IL-23 and IL-22 cytokine blockade, especially in subjects with elevated cardiovascular risk factors and/or suboptimal dietary

activation of both adaptive and innate immune cells in inflammatory diseases and cancer (Isoda et al., 2003; Kahles et al., 2014; Matsui et al., 2003) and particularly could act also on circulating monocytes in an autocrine manner in atherosclerosis. Importance of OPN in control of excessive inflammation and atherosclerosis downstream of microbial alterations was illuminated by reduction in OPN after antibiotic treatment, increase in OPN after microbial transfer from $I/23^{-/-} \rightarrow Ldlr^{-/-}$ donors and reduction in atherosclerosis after OPN neutralization.

Our data, therefore, suggests a model in which inhibition of IL-23 or IL-22 pathways results in alterations in the microbiome, which, coupled with a reduced anti-microbial, protective epithelial layer, leads to elevated serum concentration of metabolites and bacterial products, such as LPS and TMAO, promoting activation of monocytes and aortic macrophages and further progression of atherosclerosis, particularly in OPN-dependent manner. IL-23-IL-22 cytokine signaling therefore controls qualitative and quantitative characteristics of the microbiota and its pro-atherogenic metabolites and distantly suppresses atherosclerosis via regulation of intestinal homeostasis and inflammation, although we do not exclude an aorta-specific role of these cytokines. Diet and cytokine signaling-induced changes in proatherogenic metabolites regulate OPN expression, inflammation, and atherosclerosis progression. Our findings will be informative about mechanisms underlying cardiovascular adverse effects, habits (e.g., high carbohydrates, fat, or choline containing food). In the long run, inactivation of IL-23-IL-22 axis might exacerbate dormant CVD. As IL-22 is a key cytokine preventing atherosclerosis downstream of IL-23, strategies, which spare IL-22 pathway during cytokine blockade, might be justified. Most importantly, our work demonstrates mechanistic connection between cytokine signaling and host-microbiota interaction in distant regulation of prevalent, diet-driven cardiovascular disease.

STAR***METHODS**

Detailed methods are provided in the online version of this paper and include the following:

- KEY RESOURCES TABLE
- CONTACT FOR REAGENTS AND RESOURCE SHARING
- EXPERIMENTAL MODELS AND SUBJECT DETAILS
 - Animals
- METHODS DETAILS
 - Bone marrow transplantation
 - $\odot\,$ Quantification of aortic atherosclerotic lesions
 - $\,\circ\,\,$ Immune cells composition analysis by Flow Cytometry
 - Immunofluorescent and Immunohistochemistry staining analysis

⁽D) Spp1 gene expression in WT \rightarrow Ldlr^{-/-} recipients of fecal transplant from WT \rightarrow Ldlr^{-/-} or Il23^{-/-} \rightarrow Ldlr^{-/-} atherosclerotic mice.

⁽E-G) Scheme- WT $\rightarrow Ldlr^{-/-}$, $Il23^{-/-} \rightarrow Ldlr^{-/-}$, or $Il22^{-/-} \rightarrow Ldlr^{-/-}$ mice were administered with anti-OPN-antibody or control every 3 days for the last 2.5 weeks of WD feeding. Representative images of aortic root sections (F) and quantification of atherosclerotic lesion size (G) from WT $\rightarrow Ldlr^{-/-}$ (n = 7–10), $Il23^{-/-} \rightarrow Ldlr^{-/-}$ (n = 8–13) or $Il22^{-/-} \rightarrow Ldlr^{-/-}$ (n = 7–11) mice treated with anti-OPN-antibody or control (Black – PBS, Blue – IgG1k isotype control).

⁽H) Confocal microscopy of myeloid cells in aortic roots of indicated anti-OPN-treated or control mice.

⁽I) Relative gene expression in aortas from $II23^{-/-} \rightarrow LdIr^{-/-}$ (n = 6) and $II22^{-/-} \rightarrow LdIr^{-/-}$ (n = 4) mice, injected with anti-OPN-antibody or control. Gene expression was normalized to *RpL32* gene expression and then normalized to average of gene expression of untreated mice of the same genotype. Data are mean \pm SEM. - Images are representative from 3 independent experiments. Student's t-test. *p<0.05, **p<0.001, ***p<0.001. See also Figure S7.

STAR*METHODS

KEY RESOURCES TABLE

REAGENT or RESOURCE	SOURCE	IDENTIFIER	
Antibodies			
Anti-OPN (hybridoma, clone MPIIIB10)	DSHB, University of Iowa N/A		
Mouse IgG1k isotype control (clone MOPC-21)	InVivoMab, BioXCell	Cat # BE0083; RRID AB_395252	
Anti-mouse CD45-PerCP (30-F11)	Biolegend	Cat # 103130; RRID AB_893339	
Anti-mouse CD11b-eFluor 450 (M1/70)	Biolegend	Cat # 101224; RRID AB_755986	
Anti-mouse CD11c-Cy7PE (N418)	Biolegend	Cat # 117318; RRID AB_493568	
Anti-mouse TCRβ-eFluor 780 (H57-597)	eBioscience	Cat # 47-5961-82; RRID AB_1272209	
Anti-mouse CD4-PE (GK1.5)	Biolegend	Cat # 100408; RRID AB_312693	
Anti-mouse IL17A-Cy7PE (eBio17B7)	eBioscience	Cat # 25-7177-82; RRID AB_10717952	
Anti-mouse IFNγ-APC (XMG1.2)	Biolegend	Cat # 505810; RRID AB_315404	
Anti-human OPN-APC (2F10)	Invitrogen	Cat # 50-9096-41; RRID AB_2574316	
Anti-mouse CD90.2-eFluor 450 (M1/70)	Biolegend	Cat # 105324; RRID AB_2201291	
Anti-mouse TCRβ-eFluor 700 (H57-597)	Biolegend	Cat # 109224; RRID AB_1027648	
Anti-mouse CD4-APC (GK1.5)	eBioscience	Cat # 17-0041-83; RRID AB_469321	
Anti-mouse IL22-PE (1H8PWSR)	eBioscience	Cat # 12-7221-82; RRID AB_1834469	
Purified Hamster Anti-Mouse CD11c	BD Bioscience	Cat # 550283; RRID AB_393578	
FITC Rat Anti-CD11b	BD Bioscience	Cat # 553310; RRID AB_394774	
Purified anti-mouse CD3 Antibody	Biolegend	Cat # 100201; RRID AB_312658	
Anti-alpha smooth muscle Actin antibody	Abcam	Cat # ab5694; RRID AB_2223021	
Polyclonal anti-REG3G Antibody	Invitrogen	Cat # PA5-50450; RRID AB_2635903	
Polyclonal anti-Mucin 2 Antibody	Santa Cruz	Cat # Sc-15334; RRID AB_2146667	
Biotin Goat Anti-Rabbit IgG	BD Pharmingen	Cat # 550338; RRID AB_393618	
Alexa Fluor 568 donkey anti-rat IgG	Life technologies	Cat # A11077; RRID AB_2534121	
Alexa Fluor 568 donkey anti-rabbit IgG	Life technologies	Cat # A10042; RRID AB_2534017	
DyLight 649 goat anti-hamster IgG	Jackson Immunoresearch	Cat # 107-496-142; RRID AB_2337474	
Alexa Fluor 488 goat anti-rabbit IgG	Life technologies	Cat # A11034; RRID AB_2576217	
Alexa Fluor 488 goat anti-mouse IgG (H+L)	Invitrogen, Molecular probes	Cat # A11001; RRID AB_2534069	
Alexa Fluor 647 Phalloidin	Invitrogen by ThermoFisher Scientific	Cat # A22287; RRID AB_2620155	
Anti-mouse Ly6C-FITC (HK1.4)	Biolegend	Cat # 128006; RRID AB_1186135	
Chemicals, Peptides, and Recombinant Proteins			
YoYo-1 dye	ThermoFisher Scientific	Cat # Y3601	
PMA (Phorbol Myristate Acetate)	Sigma	Cat # P8139	
lonomycin	Invitrogen by ThermoFisher Scientific	Cat # I24222	
Brefeldin A 1000x Solution	eBioscience	Cat # 00-4506-51	
Yellow Live/Dead fluorescent reactive dye	Invitrogen by ThermoFisher Scientific	Cat # L34968	
Percoll	GE Healthcare	Cat # 17-0891-01	
Vancomycin Hydrochloride for Injection, USP	Hospira	Cat # NDC 0409-6531-02	
Primaxin (Imipinem)	NOVAPLUS	Cat # NDC 63323-322-93	
Neomycin trisulfate salt hydrate	Sigma	Cat # N1876	
Ciprofloxacin	Hospira	Cat # 17850-25G-F	
Ampicillin sodium salt	Sigma	Cat # A9518	
Metronidazole	Sigma	Cat # M3761	
Polymixin B Sulfate	Millipore	Cat # M5291	
Collagenase type I	Sigma	Cat # C0130	
Collagenase type XI	Sioma	Cat # C7657

EXPERIMENTAL MODELS AND SUBJECT DETAILS

Animals

All animal experiments were approved by the Animal Care Committee at FCCC. Ldlr-'- and Apoe-'- were purchased from Jackson labs. IL-23-, IL-22-deficient mice (//23p19^{-/-} referred in the text as //23^{-/-}, //22^{-/-}) were provided by Genentech Inc. IL-23R deficient mice were initially generated by G. Trinchieri (NCI/NIH) and described (Grivennikov et al., 2012). II23-/- were bred with LdIr-/- and Apoe^{-/-} mice to obtain Ldlr^{/-} x Il23^{-/-} and Apoe^{-/-} x Il23^{-/-} mice. All mice were on C57BL/6 background and were bred in house. See also Key Resources Table.

Beginning at 6 weeks of age, female and male Ldlr^{-/-} x II23^{-/-} and Apoe^{-/-} x II23^{-/-} mice were placed on WD; Ldlr^{-/-} mice were used as bone marrow recipients; II23^{-/-}, II23^{-/-}, II22^{-/-} or WT (CD45.1 C57BL6/J (JAX B6.SJL-Ptprc^B/BoyJ, Cat # 002014) were used as donors. After 4 weeks of bone marrow reconstitution, recipients were fed with Western diet (WD) (TD 88137: 15.2% kcal from protein, 42.7% kcal from carbohydrate, 42% kcal from fat, 0.2% cholesterol) https://www.envigo.com/resources/data-sheets/88137.pdf) or custom made WD (TD88137) with 1% choline (Teklad TD160118) for 16 weeks. Mice were housed under specific pathogen-free conditions in an AAALAC-approved barrier facility at Fox Chase Cancer Center (FCCC) and littermate controls were used (each cage contained WT, *II23^{-/-}* (or *II23^{-/-}*) and *II22^{-/-}* bone marrow transplanted mice). Mice were genotyped by standard PCR protocols.

IL-22 supplementation experiments

Bone marrow transplanted $II23^{-/-} \rightarrow Ldlr^{-/-}$ and WT $\rightarrow Ldlr^{-/-}$ mice fed with WD for 8 weeks were injected intraperitoneally (i.p.) every 3 days for 4 weeks with recombinant mouse IL-22 cytokine, kindly provided by Genentech Inc, (50µg per injection) or PBS. Antibiotic treatment experiments

At 12 weeks of WD feeding WT -> Ldlr^{-/-}, II23^{-/-} -> Ldlr^{-/-} and II22^{-/-} -> Ldlr^{-/-} mice were treated with water containing a mix of broadspectrum antibiotics: ciprofloxacin 0.2g/L, neomycin 1g/L, vancomycin 0.5g/L, ampicillin 1g/L, metronidazole 0.5g/L, primaxin 0.5g/L.

OPN neutralization experiments

13.5 weeks WD fed WT \rightarrow Ldlr^{-/-}, II23^{-/-} \rightarrow Ldlr^{-/-} and II22^{-/-} \rightarrow Ldlr^{-/-} mice were injected intraperitoneally (i.p.) every 3 days for 2.5 weeks with mouse OPN-antibody (purified from hybridoma, clone MPIIIB10, DSHB, University of Iowa) (100µg/mouse per injection) or control represented by either PBS or mouse IgG1k isotype control (clone MOPC-21) in 3 independent experiments.

Microbiota transfer experiments

Microbiota recipients WT \rightarrow Ldlr^{-/-} or II23^{-/-} \rightarrow Ldlr^{-/-} mice were maintained for 8 days with a mix of broad-spectrum antibiotics in drinking water (ciprofloxacin 0.2g/L, neomycin 1g/L, vancomycin 0.5g/L, ampicillin 1g/L, metronidazole 0.5g/L and primaxin 0.5g/L). 24 hours before microbiota transfer, recipient mice were placed on regular water. Microbiota from cecum of WT \rightarrow Ldlr^{-/-} or 1/23-/- -- Ldlr-/- mice fed with WD for 16 weeks was collected, weighted, resuspended at concentration 1g of feces/50ml of PBS and gavaged in PBS in 3 consecutive days after which mice were fed with WD and housed separately for 16 weeks for atherosclerosis studies.

METHODS DETAILS

Bone marrow transplantation

Recipient Ldlr-/- mice (6-8 weeks old) were irradiated in 2 equal doses of 600 rads 3-4 hours apart. Femurs and tibias of donor mice (WT, II23r-/-, II23r-/-, II23r-/-) were collected and bone marrow were isolated and resuspended in PBS under sterile conditions. After the second irradiation recipient mice were injected intravenously (i.v.) with 5*10⁶ bone marrow cell suspensions and maintained on water, containing antibiotics (neomycin and polymixin B) during first 2 weeks post-transplant. Starting 4 weeks after BMT mice were fed with WD for 16 weeks to promote the atherosclerosis development.

Quantification of aortic atherosclerotic lesions

Aortic roots were isolated, frozen in an Optimal Cutting Temperature (O.C.T.) compound (Tissue Tek (Sakura)) on dry ice and stored at -80°C. Five-micrometer frozen tissue sections were cut starting at the aortic valve plane to cover 500µm in intervals of 50µm and stained with Oil Red O/Hematoxylin/Light green as previously described. Images were obtained using Nikon Eclipse 80 imicroscope with a 4x0.2 NA objective. The lesion area was measured using Fiji software; atherosclerosis lesion area was calculated as average of lesion areas at least 8 sections for each mouse.

Immune cells composition analysis by Flow Cytometry

Aortas were isolated from WT \rightarrow *Ldlr*^{-/-}, *Il23*^{-/-} \rightarrow *Ldlr*^{-/-} and *Il22*^{-/-} \rightarrow *Ldlr*^{-/-} mice, cut into small pieces followed by digesting in 2 ml of enzymatic cocktail, containing 450 U/ml collagenase type I, 250 U/ml collagenase type XI, 120 U/ml hyaluronidase type I, 120 U/ml DNAse I in 1x HBSS and incubated in a shaker at 37°C for 55 min. Obtained single cells suspension was stained with following antibodies: CD45-PerCP (30-F11), CD11b-eFluor 450 (M1/70), CD11c-Cy7PE (N418), TCRβ-eFluor 780 (H57-597), CD4-PE (GK1.5) and LIVE/DEAD Yellow fixable dye (Invitrogen) and analyzed by flow cytometry (LSRII, BD Biosciences). For T-cell related cytokine production analysis, single-cell suspensions from aorta were stimulated in complete RPMI 1640 media with PMA+lonomycin and Brefeldin A for 5h in vitro at 37°C in a CO₂ incubator. For intracellular myeloid cells osteopontin staining, cells were stimulated in complete DMEM media with LPS (100ng/ml) for 4h in the presence of Brefeldin A. After stimulation cells were fixed and permeabilized by Cytofix/Cytoperm kit (BD), and stained with IL-17A-Cy7PE (eBio17B7), IFN_Y-APC (XMG1.2) or OPN-APC (2F10) antibody.

Lamina propria lymphocyte (LPL) isolation was performed as described before (Grivennikov et al., 2012). In brief, isolated intestines were removed and placed in ice-cold 5% fetal bovine serum (FBS) in HBSS and incubated twice in 20ml of 5mM EDTA in HBSS for 15 min at 37°C with rotation of 150 rpm. After incubation, IELs were removed by passing through a metal sieve into new tubes and the residual tissues (LPL) were chopped to make it almost homogeneous and digested in 5-6 ml collagenase type VIII (Sigma) (1mg/ml) in 5% FBS, HBSS for 35 min in shaking 37°C incubator. After incubation the solution was passed through 70µm cell strainer. Percoll gradient (40%/80%) separation of LPL was performed by centrifugation at 2200rpm for 25 min with slow acceleration and deceleration. LPL immune cells were collected from the interphase of Percoll gradient. Obtained cells suspension was stained with following antibodies: CD45-PerCP (30-F11), CD90.2-eFluor 450 (M1/70), TCRβ-eFluor 700 (H57-597), CD4-APC (GK1.5) and LIVE/DEAD Yellow fixable dye (Invitrogen) and analyzed by flow cytometry (LSRII). For IL-22 cytokine production analysis, single-cell suspensions from the LPL and aorta were stimulated in complete RPMI 1640 media with IL-23 (50ng/mL), IL-2 (5ng/mL) and IL-6 (5ng/mL) recombinant cytokines for 14 hours at 37°C in a CO₂ incubator. Brefeldin A was added to retain the cytokines within the cell for last 4h of stimulation. After stimulation cells were fixed and permeabilized by Cytofix/Cytoperm kit (BD Biosciences), and stained with IL-22-PE (1H8PWSR). Flow cytometry data were analyzed using FlowJo software.

Immunofluorescent and Immunohistochemistry staining analysis

Frozen 5µm aortic root and colon sections were fixed for 10 min in acetone (Sigma-Aldrich) at RT and placed into 1% paraformaldehyde in 100mM sodium phosphate containing 60mM lysine and 7mM sodium periodate (Sigma-Aldrich), pH 7.4 on ice. The sections were incubated with avidin/biotin blocking kit (Vector laboratories) following incubation in a 5% normal goat serum and 1% BSA (Sigma) in PBS. Aortic root sections were stained overnight at 4°C with primary antibodies: hamster anti-CD11c (HL3), rat anti-CD11b-FITC (M1/70), rat anti-CD3 (17A2) and rabbit smooth muscle actin, followed by staining with secondary antibodies for 1 h at RT: goat anti-FITC Alexa Fluor 488 (Molecular Probes), goat anti-hamster IgG DyLight 649 (Jackson Immunoresearch), goat anti-rat IgG Alexa Fluor 568 (Molecular Probes), and donkey anti-rabbit IgG Alexa Fluor 568.

Colon tissues without contents were fixed in Carnoy's fixative (60% ethanol, 30% chloroform, 10% glacial acetic acid) overnight, paraffin-embedded and stained for Mucin2 with rabbit anti-Muc2 (Santa Cruz), followed by goat anti-rabbit Alexa 488 (Life Technologies) secondary antibody staining.

RegIII_{γ} and Mucin staining were performed on colon tissues fixed in 4% Paraformaldehyde overnight and 30% Sucrose at 4°C for 12h and frozen in O.C.T. compound (Tissue Tek (Sakura)) on dry ice.

Sections were counterstained with DAPI and embedded in Prolong Gold. Images were acquired on a Leica SP8 DM6000 inverted confocal microscope using HCX PLAPO 20x and 40x oil-immersion objectives at 405 nm, 488 nm, 563 nm and 633 nm excitation wavelength. Imaris Software was employed to adjust brightness and one-step smoothing on all images in parallel.

Immunohistochemistry staining for RegIII γ was performed on frozen 5µm colon sections that were fixing for 10 min in acetone (Sigma-Aldrich). Fixed sections were incubated in 3% H₂O₂ solution in PBS at room temperature for 10 min to block endogenous peroxidase activity following by incubation with 5% normal goat serum in PBS for 1 hour at room temperature. Slides were stained overnight at 4°C with primary antibodies: rabbit anti-REGIII γ (Invitrogen) followed by staining with biotinylated secondary goat antibodies for 1 h at RT. Streptavidin-HRP (BD, Pharmingen) was added for 30 min. Sections were developed with DAB substrate (0.05% DAB and 0.015% H₂O₂ in PBS) for 3-5 min and counterstained with Hematoxylin (1-2min) and then immerged in bluing for 30 seconds. Tissue sections were dehydrated through 3 changes of alcohol (100%), 3 min each and cleared through 3 changes of xylene (Fisher Chemicals), 3 min each. Slides were mounted using Permount solution (Fisher).

For whole-mounts staining of large intestines, tissue fragments (1-2cm) were fixed in freshly prepared 4% paraformaldehyde (PFA) in PBS for 6-8h and incubated in 0.5% (wt/vol) saponin, 2% fetal bovine serum (FBS) (vol/vol), and 0.09% (wt/vol) azide in PBS for at

least 18 h at 4°C. The same buffer was used for subsequent incubations with fluorescently labeled Phalloidin (Alexa Fluor 647) and YOYO-1 iodide (491/509) overnight at 4°C followed by 2h incubation at 37°C. Samples were washed with PBS and analyzed by microscopy.

TUNEL assay/Immunofluorescence staining

Frozen 5µm aortic roots were fixing for 10 min in acetone (Sigma-Aldrich) at RT and placed into 1% paraformaldehyde in 100mM sodium phosphate containing 60mM lysine and 7mmM sodium periodate (Sigma-Aldrich) pH 7.4 on ice. Then slides were permeabilized with freshly prepared 0.1% Triton X-100, 0.1% sodium citrate solution and incubated with TUNEL reaction mixture for 60 minutes at 37°C in the dark. The sections were incubated with avidin/biotin blocking kit (Vector laboratories) followed by incubation in a 5% normal goat serum and 1% BSA (Sigma) in PBS. Aortic root sections were stained overnight at 4°C with primary antibodies: rat anti-CD11b-FITC (M1/70, BD Bioscience) followed by staining with secondary antibodies for 1 h at RT: goat anti-FITC Alexa Fluor 488 (Molecular Probes).

Gene expression analysis

The tissues (aorta, intestine or spleen) were homogenized with RNAse/DNase free 2.8mm Ceramic Beads using Omni Bead Ruptor 24 in PureZOL RNA Isolation Reagent (Bio-Rad Laboratories) followed by RNA isolation using Aurum Total RNA Fatty and Fibrous Tissue kit (Bio-Rad Laboratories) according to manufacturer's protocol. First strand cDNA was synthetized using the iScript Reverse Transcription Supermix (Bio-Rad Laboratories). Gene expression was analyzed by SYBR green real-time polymerase chain reaction (Bio-Rad Laboratories) using primers for *RpL32*, *Spp1*, *II1b*, *Tnf*, *Ifng*, *II17a*, *II22*, *Ccl2*, *Ccl5*, *Cxcl1*, *Reg3b*, *Reg3g*, *Muc2*, *Cd36*, *Itgam*, *II12a*, *II12b*, *Mrc1*, *Chi3l1*, *Chi3l3*, *Retnla*, *Abca1*, *Abcg1*. Gene expression was normalized to *RpL32* expression. Data were analyzed using Prism statistical software (GraphPad).

Microbiome analysis

16S rRNA sequencing: To analyze 16S rRNA of gut microbiota, bacterial DNA was isolated from a fecal microbiome of WT, *II23^{-/-}* and *II22^{-/-}* bone marrow transplanted *Ldlr^{-/-}* mice. The stools were homogenized with RNAse/DNase free 2.8mm Ceramic Beads using Omni Bead Ruptor 24 in ASL buffer (stool lysis buffer) (Qiagen) followed by DNA isolation using QIAamp DNA stool Mini Kit (Qiagen) according to manufacturer's protocol. QPCR was carried out using universal or bacterial strain-specific primers for 16S rRNA genes. The V4 region of the 16S rDNA gene was amplified by two round amplification PCR using Phusion High-Fidelity DNA-polymerase (NEB) with 100ng of input DNA. First round PCR (15 cycles):

515F TCGTCGGCAGCGTCAGATGTGTATAAGAGACAGCCTACGGGNGGCWGCAG

806R GTCTCGTGGGCTCGGAGATGTGTATAAGAGACAGGACTACHVGGGTATCTAATCC

Second round PCR (10 cycles) with i5 and i7 Illumina barcode sequences:

AATGATACGGCGACCACCGAGATCTACAC-i5-TCGTCGGCAGCGTC

CAAGCAGAAGACGGCATACGAGAT-i7-GTCTCGTGGGCTCGG

Amplicones were purified between and after the PCR reactions with Agencourt AMPure XP (Beckman Coulter, Inc.), libraries were quantified using KAPA Library Quantification Kit for Illumina Platforms (Kapa Biosystems) and size was estimated using Agilent Tapestation 4200 (Agilent). Libraries were pooled at equimolar concentration using Epmotion 5075 tmx automatic liquid handling machine (Eppendorf) and sequenced with 5% PhiX library added to the pool on Illumina MiSeq machine according to manufacture instructions using v3 kit (600 cycles). Fastq files were generated on Basespace (Illumina). On average 100,000 reads were obtained per sample, and after quality control filtering; on average 90,000 reads per sample were processed further. Chimeric sequences were filtered out of the FASTQ files containing the 16S rRNA gene sequences using the USEARCH (version 8.1.) utility's UCHIME implementation and the 'gold' database (version microbiomeutil-r20110519). The reads, thus filtered, were then binned into operational taxonomic units (OTUs) at 97% similarity using USEARCH's cluster_otus command. QIIME (1.9.1) scripts were used to classify and align the obtained OTUs (Namasivayam et al., 2017). The assign_taxonomy.py script was used to assign taxonomy using the default RDP method (Wang et al., 2007) and GreenGenes database (DeSantis et al., 2006). The statistical differences between the groups were estimated with non-parametric Mann-Whittney test and p-values were corrected for multiple tests using q-value 0.05 as a cutoff and data was visualized using heatmaps and PCA plots (Partek 6.6).

Metagenomic whole genome shotgun (WGS) sequencing

Metagenomic sequencing provides species-level resolution of bacteria, and depending on sequence depth, can quantify the nearcomplete genomic content of the collection of microbes in a particular sample, referred to as the sample's metagenome.

Whole genome shotgun (WGS) sequencing utilized the same extracted bacterial genomic DNA used for 16S rRNA gene compositional analysis and was done at Microbiome Core at NCI. Briefly, metagenomic DNA obtained from 16 samples was used to build paired-end shotgun sequencing libraries with the Illumina Nextera FLEX kit. Libraries were sequenced on the Illumina NextSeq 500 platform yielding 2 x 75 bp reads totaling between 2.9 and 4.9 Gbp of raw data. For each sample, raw reads were adapter trimmed and quality clipped using Trimmomatic v.0.36 (Bolger et al., 2014). Trimmed reads were then aligned against the *Mus musculus* complete genome using bowtie v.2-2.3.4. Reads which did not align to the mouse genome were considered as pertaining to the microbiome and were used as input for read assembly using MEGAHIT v1.1.1 (Li et al., 2015). The mean assembly rate for samples was $69\% \pm 13\%$ of total reads being assembled into contigs of at least 500 bp. Contigs resulting from assembly were taxonomically classified by k-mer spectrum with kraken v.1.1 (Wood and Salzberg, 2014) using a custom built k-mer database comprising of all complete plus draft genomes present in NCBI's GenBank of bacteria, archaea, viruses, fungi, protozoa, plus the genomes of *Homo sapiens* and *Mus musculus*. Contigs identified as being *Mus musculus* were discarded. Contigs were annotated using prokka v.1.12 (Seemann, 2014) and the predicted metaproteome was functionally annotated using interproscan v.5.29-68.0 (Hunter et al., 2009). The trimmed reads used as input for assembly were then aligned against the contigs using bowtie2 to gauge sequencing depth for each contig. Reads, which did not align to any contig (unassembled reads), were collected and themselves taxonomically classified by kraken using the aforementioned custom-built k-mer database. The relative abundance for each taxon was calculated as being the relative proportion of bases attributed to that taxon, coming from either unassembled reads or reads built into contigs, out of the total amount of bases sequenced for that sample. Relative abundances were expressed as parts per million.

The relative abundance of functions (taxonomy independent) was calculated in a similar manner, but considering only bases assembled into contigs, as each protein was predicted *ab initio* from the contigs. The number of bases sequenced for each protein-coding gene was measured from the contig sequencing depth. Because all the proteins were functionally characterized by Interproscan as to their functional domain signatures, the relative abundance of each functional protein signature within a sample was computed as being the relative proportion (expressed in parts per million) of the sum of the sequencing depths of all proteins within the sample. It can thus be interpreted as the "dose" of a functional signature within the sample, independent of taxonomy.

Additional factor accounting for cage effect was added in the statistical model testing for unique and common effect of IL-22 and IL-23 deficiency in atherosclerotic mice.

Serum analysis of bacterial endotoxin (LPS)

Blood samples were drawn from WT, *II23^{-/-}* or *II22^{-/-}* transplanted *Ldlr^{-/-}* mice and serums were collected via centrifugation for 10 min. Serum endotoxin level was determined using Pierce LAL Chromogenic Endotoxin Quantification Kit (Thermo Scientific) according to manufacture protocol. The results were analyzed using spectrophotometer.

TMAO analysis

TMAO levels were quantified by stable isotope dilution liquid chromatography with on line electrospray ionization tandem mass spectrometry on a Shimadzu 8050 triple quadrupole mass spectrometer interfaced with UHPLC using d9(trimethyl)-TMAO as internal standard, as previously described (Wang et al., 2014b).

Metabolomics

Mass spectrometry analysis was performed by the Proteomics and Metabolomics Facility at the Wistar Institute. Polar metabolites were extracted from serum using 80% methanol, and targeted quantitation of metabolites was performed on a SCIEX 5500 QTRAP triple quadrupole mass spectrometer equipped with a Turbo V source and coupled to a Shimadzu Nexera UHPLC system. Five microliters of each sample were injected onto a ZIC-pHILIC 2.1-mm i.d \times 150 mm column (EMD Millipore). Buffer A was 20 mM ammonium carbonate, 0.1% ammonium hydroxide; and buffer B was acetonitrile. The chromatographic gradient was run at a flow rate of 0.150 ml/min for 80-20% B over 20 min, 20-80% B over 0.5 min, and hold at 80% B for 7.5 min. Metabolites were targeted in positive and negative ion modes for a total of 163 selected reaction monitoring transitions. Electrospray ionization voltage was +5500 V in positive ion mode and -4500 V in negative ion mode. A minimum of 8 data points was acquired per detected metabolite. Peak areas from the total ion current for each metabolite-selected reaction monitoring transition were integrated using the MultiQuant v3.0.2 software (SCIEX).

Metabolome detection intensity levels were quantile normalized and log2-transformed. Significance of changes were tested using Limma package (Ritchie et al., 2015) version 3.36.1 combining mice genders and separately and results passing p<0.05 threshold were called significant. Additional factor accounting for cage effect was added in the statistical model testing for unique and common effect of IL-22 and IL-23 deficiency in atherosclerotic mice. Results related to TMAO pathway were reported as fold changes with significant effects highlighted.

LPS and TMAO supplementation

Beginning at 6 weeks of age, female and male *Ldlr^{-/-}* were fed with a WD for 6 weeks and then injected i.p. with LPS (50µg per injection), TMAO (250 µl of 100µM solution per injection) or both metabolites together every 3 days for additional 3 weeks of WD feeding. After that, changes in atherosclerosis progression and inflammatory gene expression were analyzed.

For the *ex vivo* experiments explanted aortas from C57BL/6 mice were stimulated in serum free DMEM media with LPS (100ng/ml), TMAO (200ng/ml) or both for 8h at 37°C in CO₂ incubator.

For acute LPS and TMAO exposure studies, C57BL/6 female and male mice were injected with LPS (50µg) and TMAO (250 µl of 100µM solution per injection) and blood was collected after 4 hours following by immunomagnetic isolation of Ly6C positive monocytes using Easy Sep FITC Positive Selection Kit (StemCell Technologies) according to the manufacture protocol. Sorted cells were lysed in RLT buffer following with RNA isolation and Q-RT-PCR analysis.

Scanning Electron Microscopy

Proximal colon and terminal ileum were collected from WT $\rightarrow Ldlr^{-/-}$, $ll23^{-/-} \rightarrow Ldlr^{-/-}$ and $ll22^{-/-} \rightarrow Ldlr^{-/-}$ mice fed with WD for 16 weeks for SEM imaging. Intestinal samples were fixed in 2.5% glutaraldehyde in PBS (pH 7.4) for 10 min. Tissue samples were washed thoroughly in PBS for 15 min. Further, tissues were fixed in 1% Osmium tetraoxide (OsO₄) in PBS for 60 min. Samples were then dehydrated with different concentration of ethanol 30%, 50%, 70%, 90% for 15 min and then samples were critical point dried. Finally, samples were sputter coated with gold. Samples were visualized using Field Emission Scanning Electron Microscope (JEOL JSM 6335F) at the magnification of 550X and 1000X.

QUANTIFICATION AND STATISTICAL ANALYSIS

Data were analyzed using Prism software (GraphPad). Student's 2-tailed T-test and Wilcoxon signed-rank test was used to compare fold induction of gene expression by real-time PCR. ANOVA test was used for multiple comparisons.

Microbiota composition was analyzed and visualized using Partek, Matlab and R packages. Standard statistical tests, such as t-test, ANOVA, PERMANOVA, PCA, t-SNE and others were performed and visualized using scatter plots and heatmaps. Picrust analysis was performed on biome file. Pathways outputs were analyzed using Partek and R. Data are expressed as mean \pm SEM. *p<0.05, ** p <0.01, *** p <0.001. P value <0.05 was considered significant.

DATA AND SOFTWARE AVAILABILITY

The accession number for the raw data files for 16SRNA and metagenomic microbiome sequencing analysis reported in this paper is NCBI Bioproject. Accession number PRJNA488231.
